Swiggy Order Analytics | Power BI Project

1. Project Overview

The Swiggy Order Analytics project is a Power BI business intelligence solution designed to analyze food-order transactions, customer behavior, restaurant performance, payment methods, delivery performance, and order status. The objective is to convert raw order, customer, and restaurant data into an interactive dashboard that supports operational and business analysis.

2. Business Problem

Food-delivery businesses generate large volumes of transactional data, but raw data does not provide an immediate view of revenue performance, order volume, customer activity, restaurant contribution, payment preferences, cancellations, or delivery efficiency. Stakeholders need a single dashboard to identify patterns and compare performance across cities, restaurants, cuisines, payment methods, and time periods.

3. Problem Statement

Build an interactive Power BI dashboard that provides a consolidated view of Swiggy order performance and enables users to monitor revenue, order volume, average order value, cancellation rate, delivery time, restaurant contribution, payment-method share, city performance, cuisine-level order status, and the relationship between restaurant ratings and order value.

4. Key Business Questions

- What is the total revenue generated from orders?
- How many orders were placed?
- What is the average order value?
- What percentage of orders were cancelled?
- What is the average delivery time?
- Which restaurants contribute the most net revenue?
- How does revenue change over time?
- Which payment methods account for the largest share of orders?
- How do revenue and order volume vary by city?
- How are order statuses distributed across cuisines?
- Is there a visible relationship between restaurant rating and average order value?

5. Data Sources

The project uses three logical tables:

Table	Key Columns	Purpose
-------	-------------	---------

Orders	OrderID, CustomerID, RestaurantID, OrderDate, OrderTime, DeliveryTimeMin, ItemsCount, OrderValue, DiscountAmount, DeliveryFee, PaymentMethod, OrderStatus	Transaction-level order analysis
Customers	CustomerID, CustomerName, Gender, Age, City, SignupDate	Customer segmentation and geographic analysis
Restaurants	RestaurantID, RestaurantName, City, Cuisine, Rating, CostForTwo, FoodType	Restaurant and cuisine analysis

6. Expected Outcome

A clean, interactive Power BI dashboard with KPI cards, trend analysis, restaurant ranking, payment-method share, city-level performance, cuisine/status analysis, and rating-versus-order-value analysis. The dashboard should allow users to filter the analysis using Payment Method, City, Order Status, Cuisine, and Order Date.
